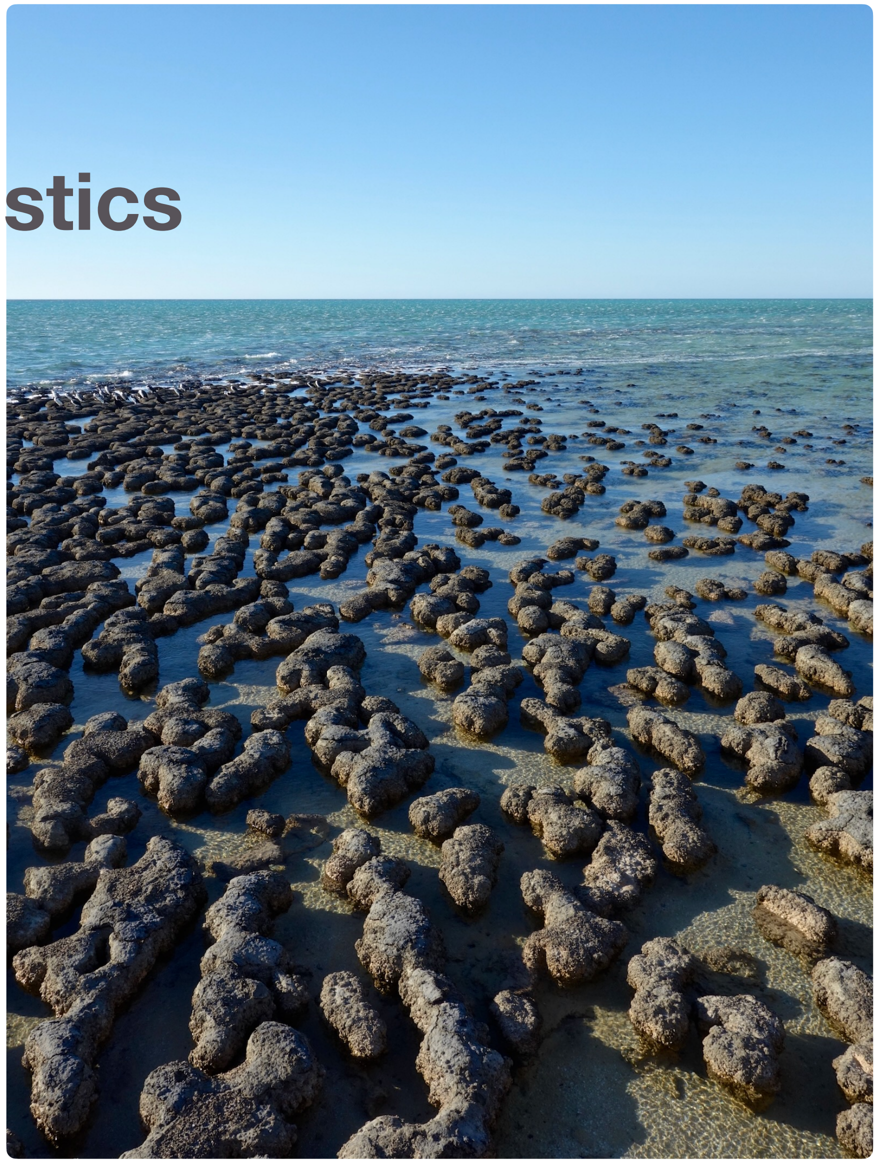
Exercises in Marine Ecological Genetics

03. Population structure and *F*-statistics



- Calculate *F*-statistics in R
- Test for genetic differentiation
- Visualize population structure

Martin Helmkampf

https://github.com/mhelmkampf/meg26

Today's objectives

By the end of this session, you will be able to:

Connecting to the cluster via SSH

```
### Establish SSH connection to cluster using your course account
ssh user1234@rosa.hpc.uni-oldenburg.de  # please adjust user name

### Enter password (invisible)
```

...

```
### Either: Download course materials to course account using Git (first time)
git clone https://github.com/mhelmkampf/meg26.git

### Or: Update git repository (if it already exists)
cd meg26
git pull
```

Keep following instructions in course script (02_hwe.R)

Genepop file format

Recap

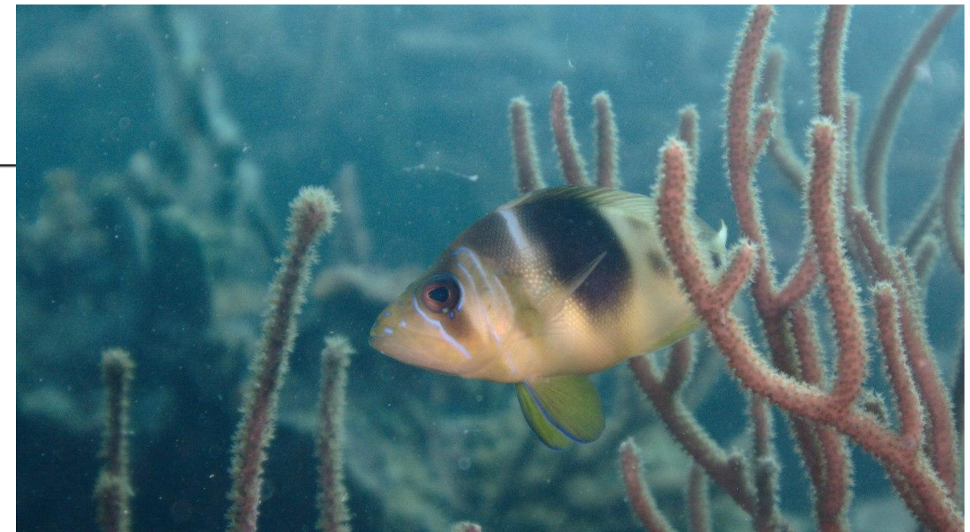
Locus names

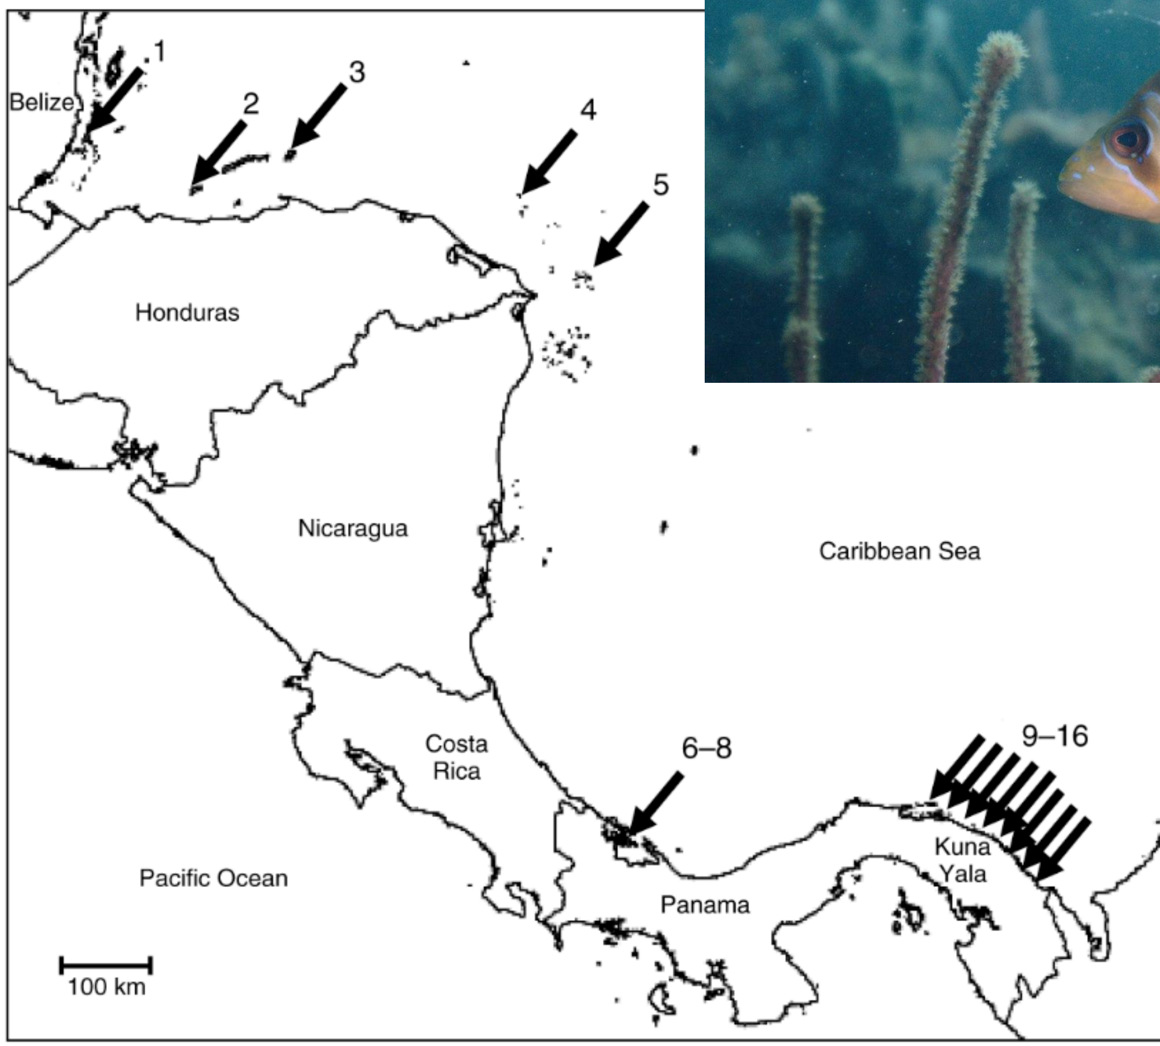
Sample / population

Alleles (000 = missing data)

Barred hamlet (*H. puella*) microsatellite dataset

Recap





Ecology, 90(11), 2009, pp. 3087–3098

Estimating dispersal from genetic isolation by distance in a coral reef fish (*Hypoplectrus puella*)

Oscar Puebla,[1,2,3] Eldredge Bermingham,[1,2] and Frédéric Guichard[2]

- 10 highly variable microsatellite loci
- 854 individuals
- 15 Caribbean locations

Useful R functions for population genetics

Recap

Import Genepop file as genind object

```
x <- read.genepop(path_to_file, ncode = n)                # adegenet package
```

Object name

No. of characters encoding each allele

Name of Genepop file (including path)

Locus statistics (e.g. no. of alleles, Simpson's index, heterozygosity, evenness)

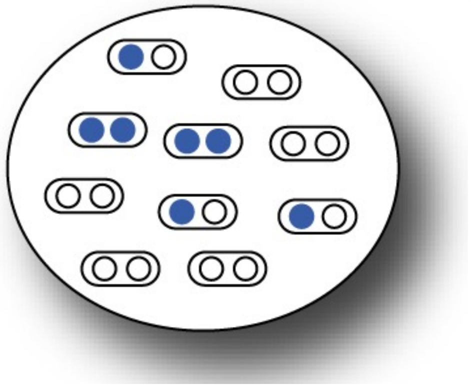
```
locus_table(x)                                              # poppr package
```

Fixation index

Lecture

HETEROZYGOSITY

In one population



H_o = proportion of heterozygote individuals, observed heterozygosity

$H_e = 2pq = 1 - p^2 - q^2$, expected heterozygosity (assuming HW equilibrium)

$$F = \frac{H_e - H_o}{H_e}$$

Fixation index: *proportion by which heterozygosity is reduced or increased relative to the heterozygosity of a population at HW equilibrium with the same allele frequencies.*

Divided by H_e –> *proportion* (of expected heterozygosity)

Varies between -1 and 1

$F < 0$: heterozygote excess

$F > 0$ heterozygote deficit (homozygote excess)

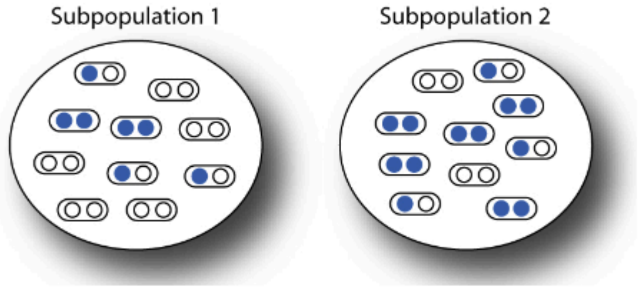
May be averaged over several loci –> reduces bias

May be extended to k alleles

Extension to multiple subpopulations

Lecture

In *n* subpopulations



$$H_I = \frac{1}{n}\sum_{i=1}^{n} \hat{H}_i$$ Mean observed heterozygosity within subpopulations

$$H_S = \frac{1}{n}\sum_{i=1}^{n} 2p_i q_i$$ Mean expected heterozygosity within subpopulations (assuming HW within subpops)

$$H_T = 2\bar{p}\bar{q}$$ Expected heterozygosity of the total population (assuming HW within the total pop)

$\hat{H}_i$ observed heterozygosity in population i $p_i(q_i)$ frequency of allele A(a) in population i

$\bar{p}(\bar{q})$ mean frequency of allele A(a) $n:$ number of subpopulations

$$F_{IS} = \frac{H_S - H_I}{H_S} \qquad F_{ST} = \frac{H_T - H_S}{H_T} \qquad F_{IT} = \frac{H_T - H_I}{H_T}$$

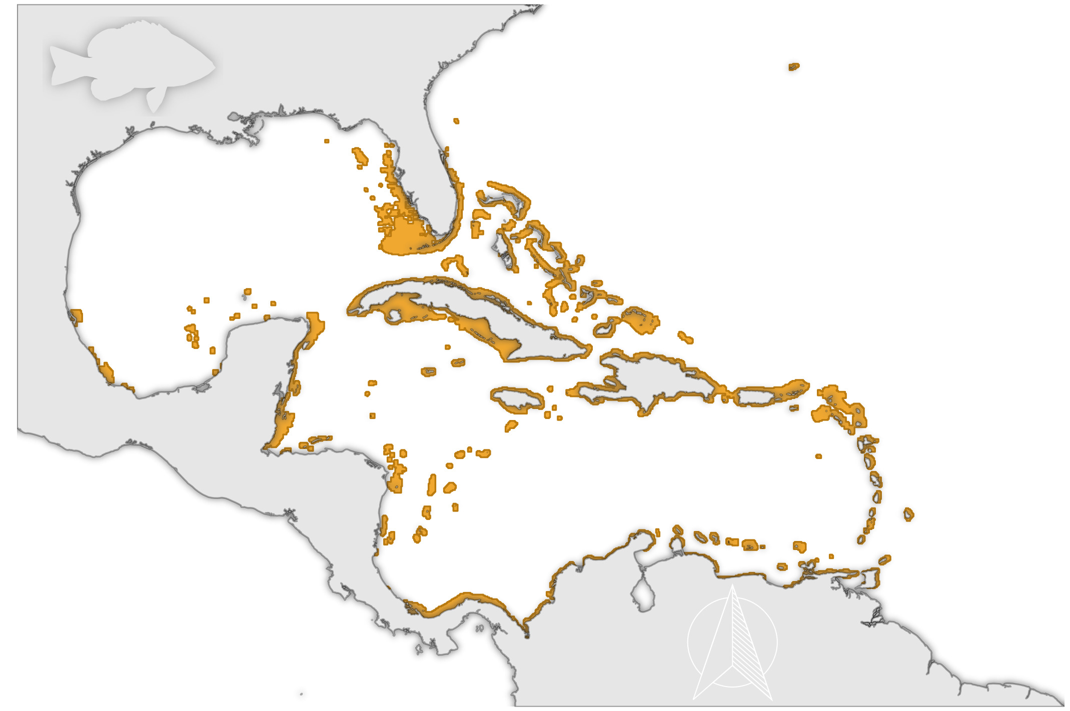
F_{IS} Average difference between observed and Hardy–Weinberg expected heterozygosity within each subpopulation (due to non-random mating)

F_{ST} Reduction in heterozygosity due to subpopulation divergence of allele frequencies

F_{IT} *Combined departure from HW expected genotype frequencies due to non-random mating within subpopulations and divergence of allele frequencies among subpopulations*

Hamlets, models for a marine radiation

- Complex of 18+ species (genus *Hypoplectrus*)
- Endemic to coral reefs in wider Caribbean
- Little ecological differentiation
- Differ strongly by color pattern
- Reproductively isolated by assortative mating



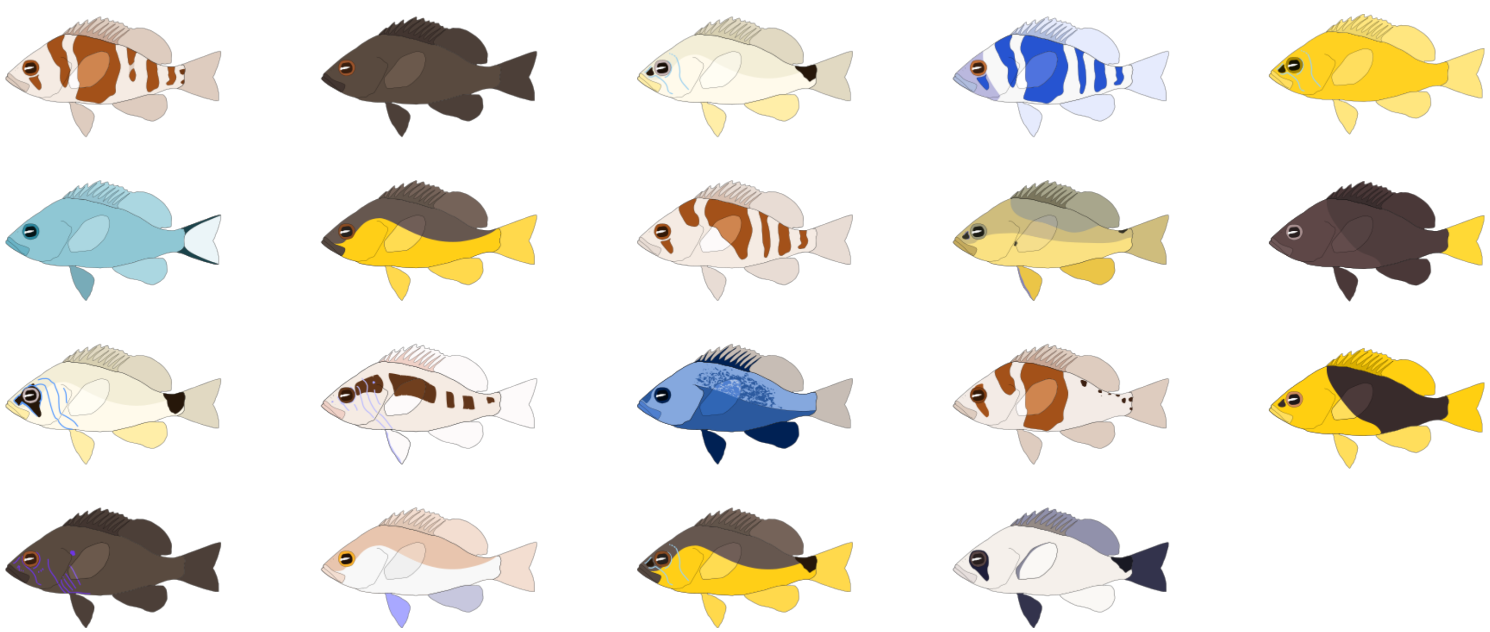


Photo by Allison & Carlos Estape

Illustrations and map by Kosmas Hench, data from biogeodb.stri.si.edu

F_{ST} range across organisms

Exercises 1–3

Species	$\hat{F}_{ST}$	$\widehat{N_e m}$	Reference
Amphibians			
Alytes muletansis (Mallorcan midwife toad)	0.12–0.53	1.8–0.2	Kraaijeveld-Smit et al. 2005
Birds			
Gallus gallus (broiler chicken breed)	0.19	1.0	Emara et al. 2002
Mammals			
Capreolus capreolus (roe deer)	0.097–0.146	2.2–1.4	
Homo sapiens (human)	0.03–0.05	7.8–4.6	
Microtus arvalis (common vole)	0.17	1.2	
Plants			
Arabidopsis thaliana (mouse-ear cress)	0.643	0.1	
Oryza officinalis (wild rice)	0.44	0.3	
Phlox drummondii (annual phlox)	0.17	1.2	
Prunus armeniaca (apricot)	0.32	0.5	
Fish			
Morone saxatilis (striped bass)	0.002	11.8	Brown et al. 2005
Sparisoma viride (stoplight parrotfish)	0.019	12.4	Geertjes et al. 2004
Insects			
Drosophila melanogaster (fruit fly)	0.112	2.0	Singh and Rhomberg 1987
Glossina pallidipes (tsetse fly)	0.18	1.1	Ouma et al. 2005
Heliconius charithonia (butterfly)	0.003	79.8	Kronforst and Flemming 2001
Corals			
Seriatopora hystrix	0.089–0.136	2.6–1.6	Maier et al. 200

F_{ST}	Subpopulations are …
< 0.15	very similar
0.15 – 0.25	similar
> 0.25	distinct

Barred hamlet (*H. puella*) microsatellite dataset

Bonus

Hamlets are simultaneous hermaphrodites with external fertilization. Discuss whether self-fertilization occurs regularly according to *F*-statistics.

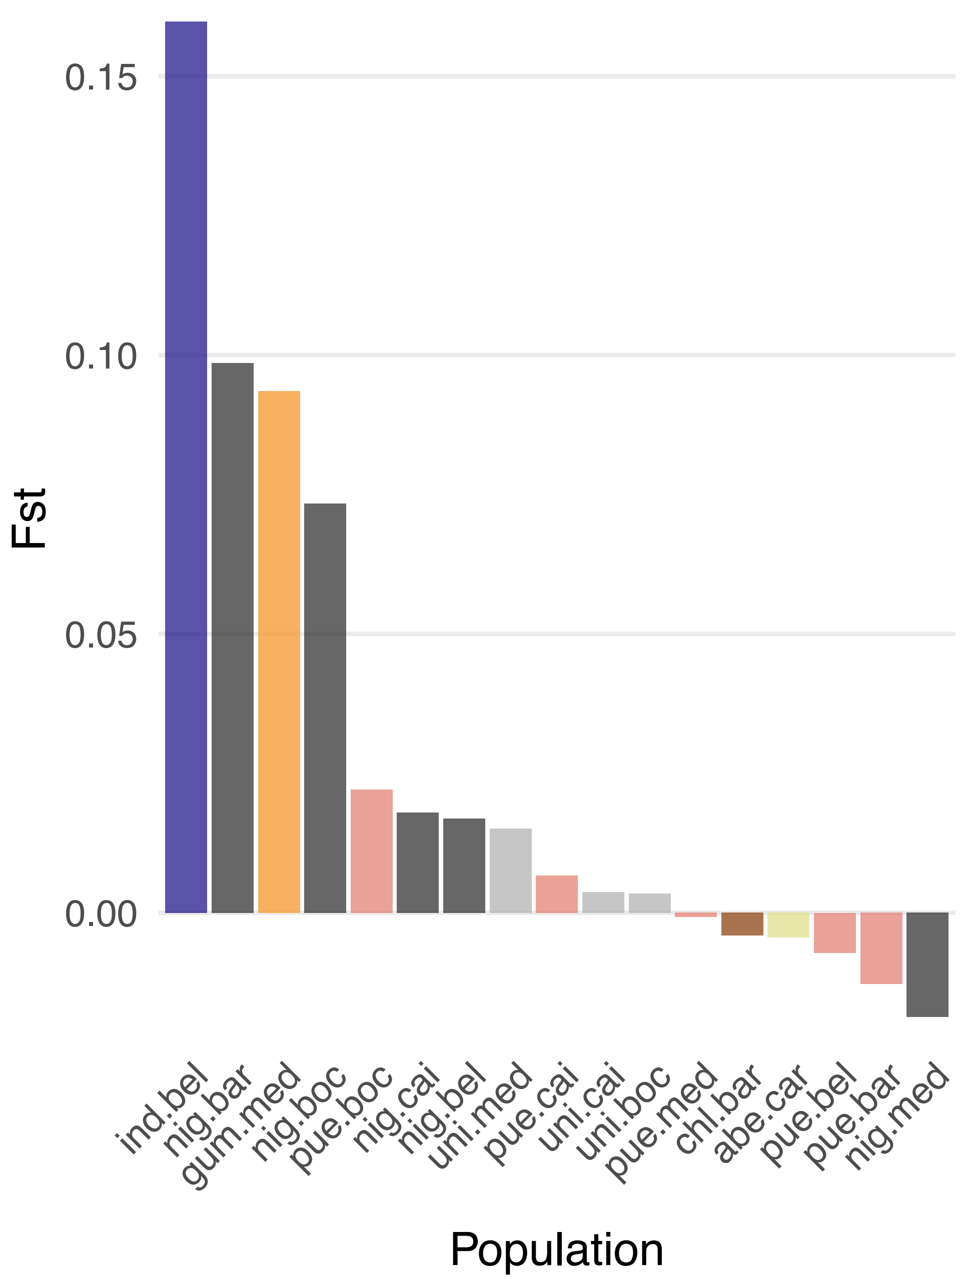
Visualize population structure

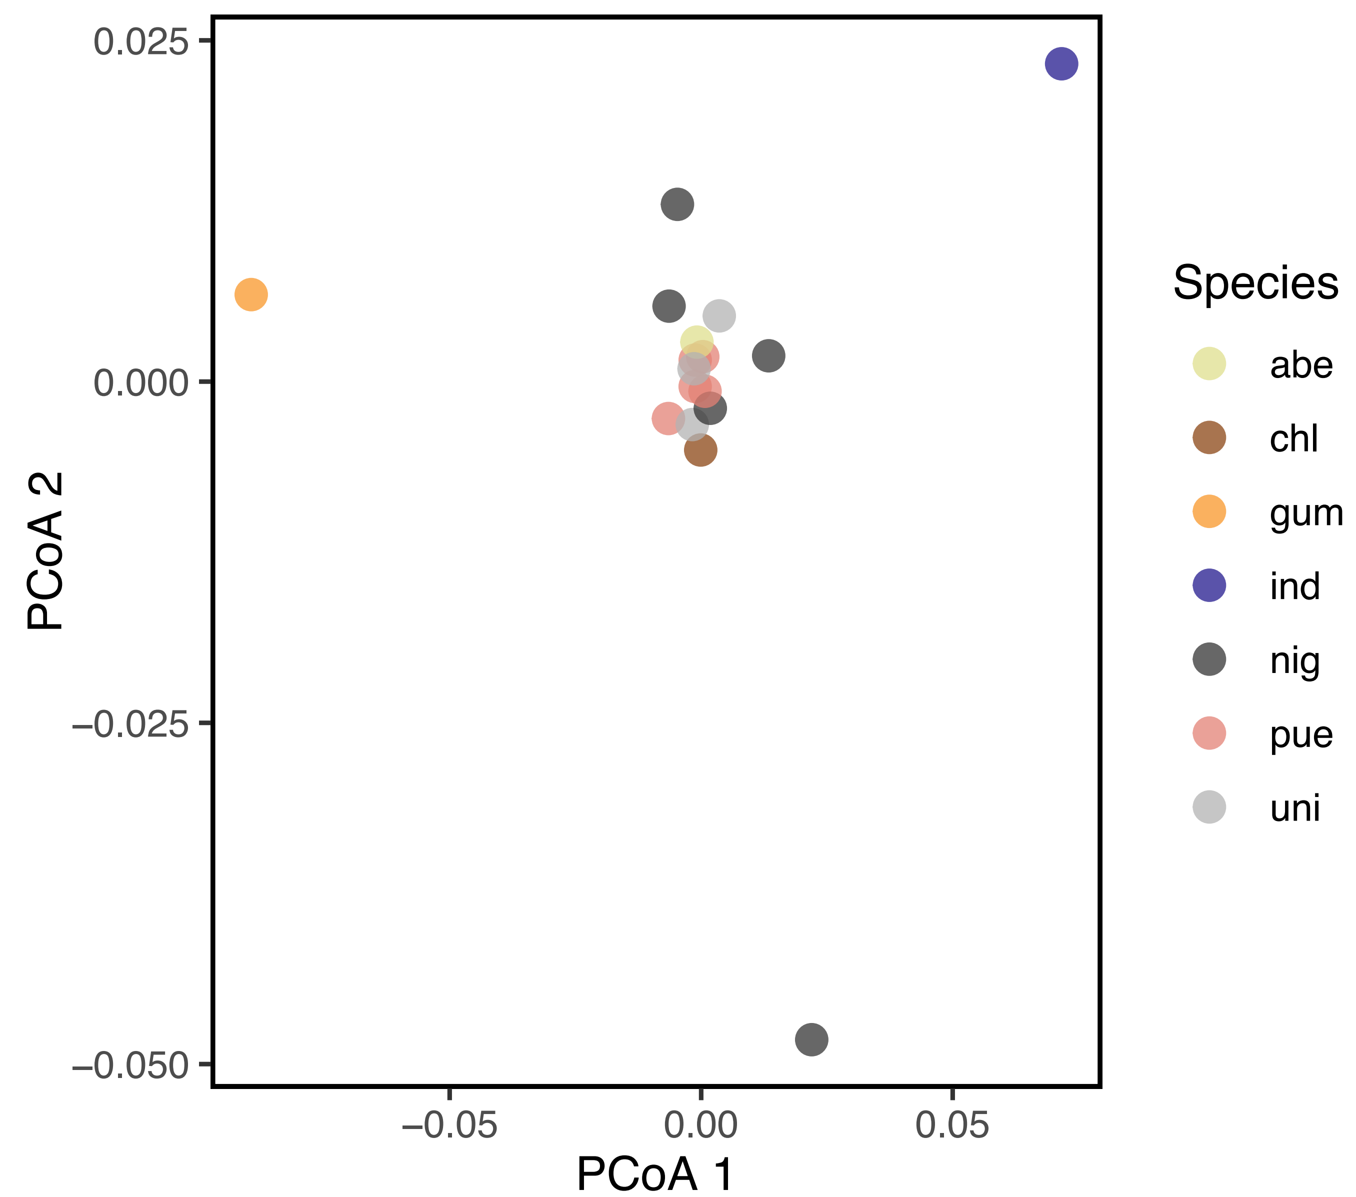
Exercise 3

- Reduce high-dimensional genetic data to 2–6 axes for visualization
  - Calculate pairwise distances and project samples or subpopulations into a coordinate system that preserves these distances (**PCoA**)
  - Find axes (principal components) that capture the maximum variance in genotype data (**PCA**)
- Individuals or subpopulations cluster by genetic similarity, revealing structure across populations or species
- PCoA is suited for subpopulations and microsatellite data, while PCA can be used on the level of individuals and SNP genotypes

Visualize population structure

Exercises 2/3





Useful R functions for population genetics

Summary

Calculate summary F_{ST}

```
pegas::Fst(as.loci(x))                                    # x = genind object
```

Calculate pairwise F_{ST}

```
genet.dist(x, method = "Nei87")
```

Calculate population-specific F_{ST}

```
betas(x)
```

New R concepts: tidyverse and ggplot

Summary

Tidyverse pipes

```
tb <- df %>%         # assign to new object (copy)
   mutate() %>%      # 1st operation
   arrange() %>%     # 2nd operation
   select()          # 3rd operation
```

Basic ggplot syntax

```
ggplot(data = tb, aes(x = var1, y = var2)) +  # data structure (map variables)
   geom_bar() +     # geometric shapes representing the data
   labs() +         # set plot and axis labels
   guides() +       # customize plot legend
   theme()          # customize non-data, e.g. fonts, gridlines
```

Key takeaways

Summary

- *F*-statistics describe how genetic variation is split within individuals, within populations, and between populations
- F_{ST} measures **genetic differentiation** (how much populations have diverged) by comparing allele frequency variation within vs. between populations (0–1)
- F_{ST} can be summarized as a single statistic, calculated pairwise between populations, or estimated per population to assess how distinct each population is
- Investigating population structure helps **disentangle** the effects of selection, drift, migration and demographic history
- Identifying distinct genetic populations is important for the **conserving genetic diversity** and informing management units

Course outline

Preliminary, may be subject to change

Class	Date	Topics	Script
01	Apr 10	Introduction and setup	01_intro.R
